

Feature Detection and System Identification

Laser triangulation based deposition feature detection and steady-state input-output modelling

Ali Toyserkani, Gijs Houtam

Goals

Proof-of-Concept:

Is it possible to make a low-cost vision sensing technique able to detect deposition height and width accurately in a real-time setup?

Hardware:	Software:
<ul style="list-style-type: none">• Low-Cost components	<ul style="list-style-type: none">• Fast Detection Algorithm
<ul style="list-style-type: none">• Applicable to existing 3D-printers	<ul style="list-style-type: none">• Constant execution time
<ul style="list-style-type: none">• Commercially attractive	

Laser Triangulation

- Angular positioning exposes deposition geometry
- Many implementations possible

Reverse Geometry:

- Good Camera Focusing
- Good Height Resolution through high α

Camera Visuals

Problem Sources:	Opportunities:
<ul style="list-style-type: none">• Laser Lens distortion → Noise	<ul style="list-style-type: none">• Separate pixel by intensity
<ul style="list-style-type: none">• Pixel Saturation → No difference	<ul style="list-style-type: none">• Use lens distortions as Pattern
<ul style="list-style-type: none">• Reflection or Absorption	

White object

Transparent object

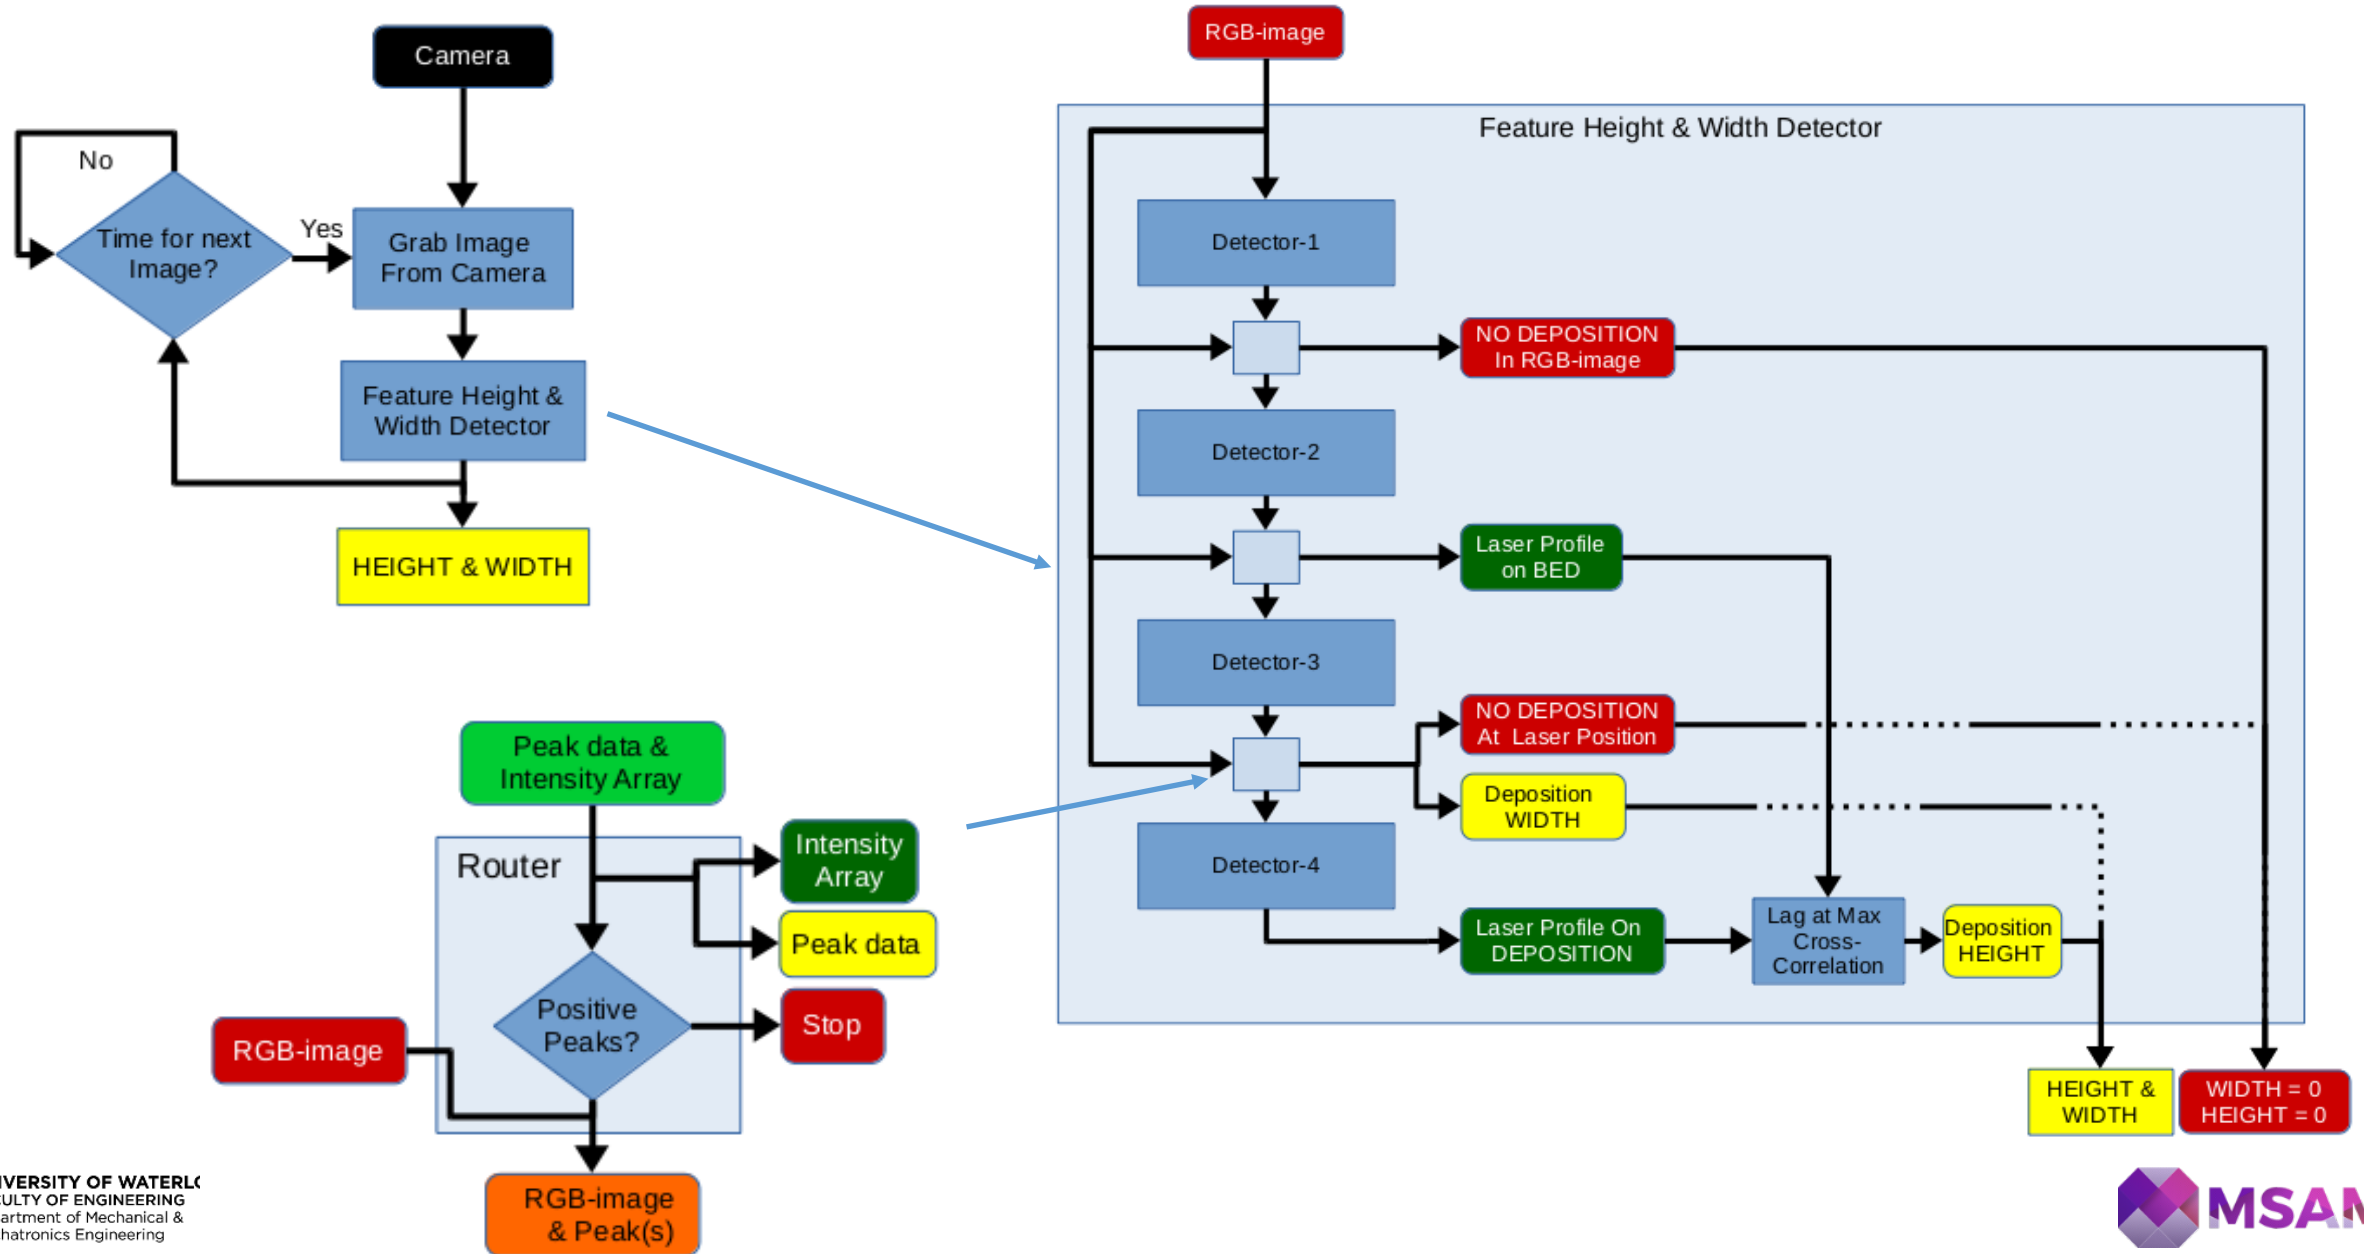

Black object

Computational matters

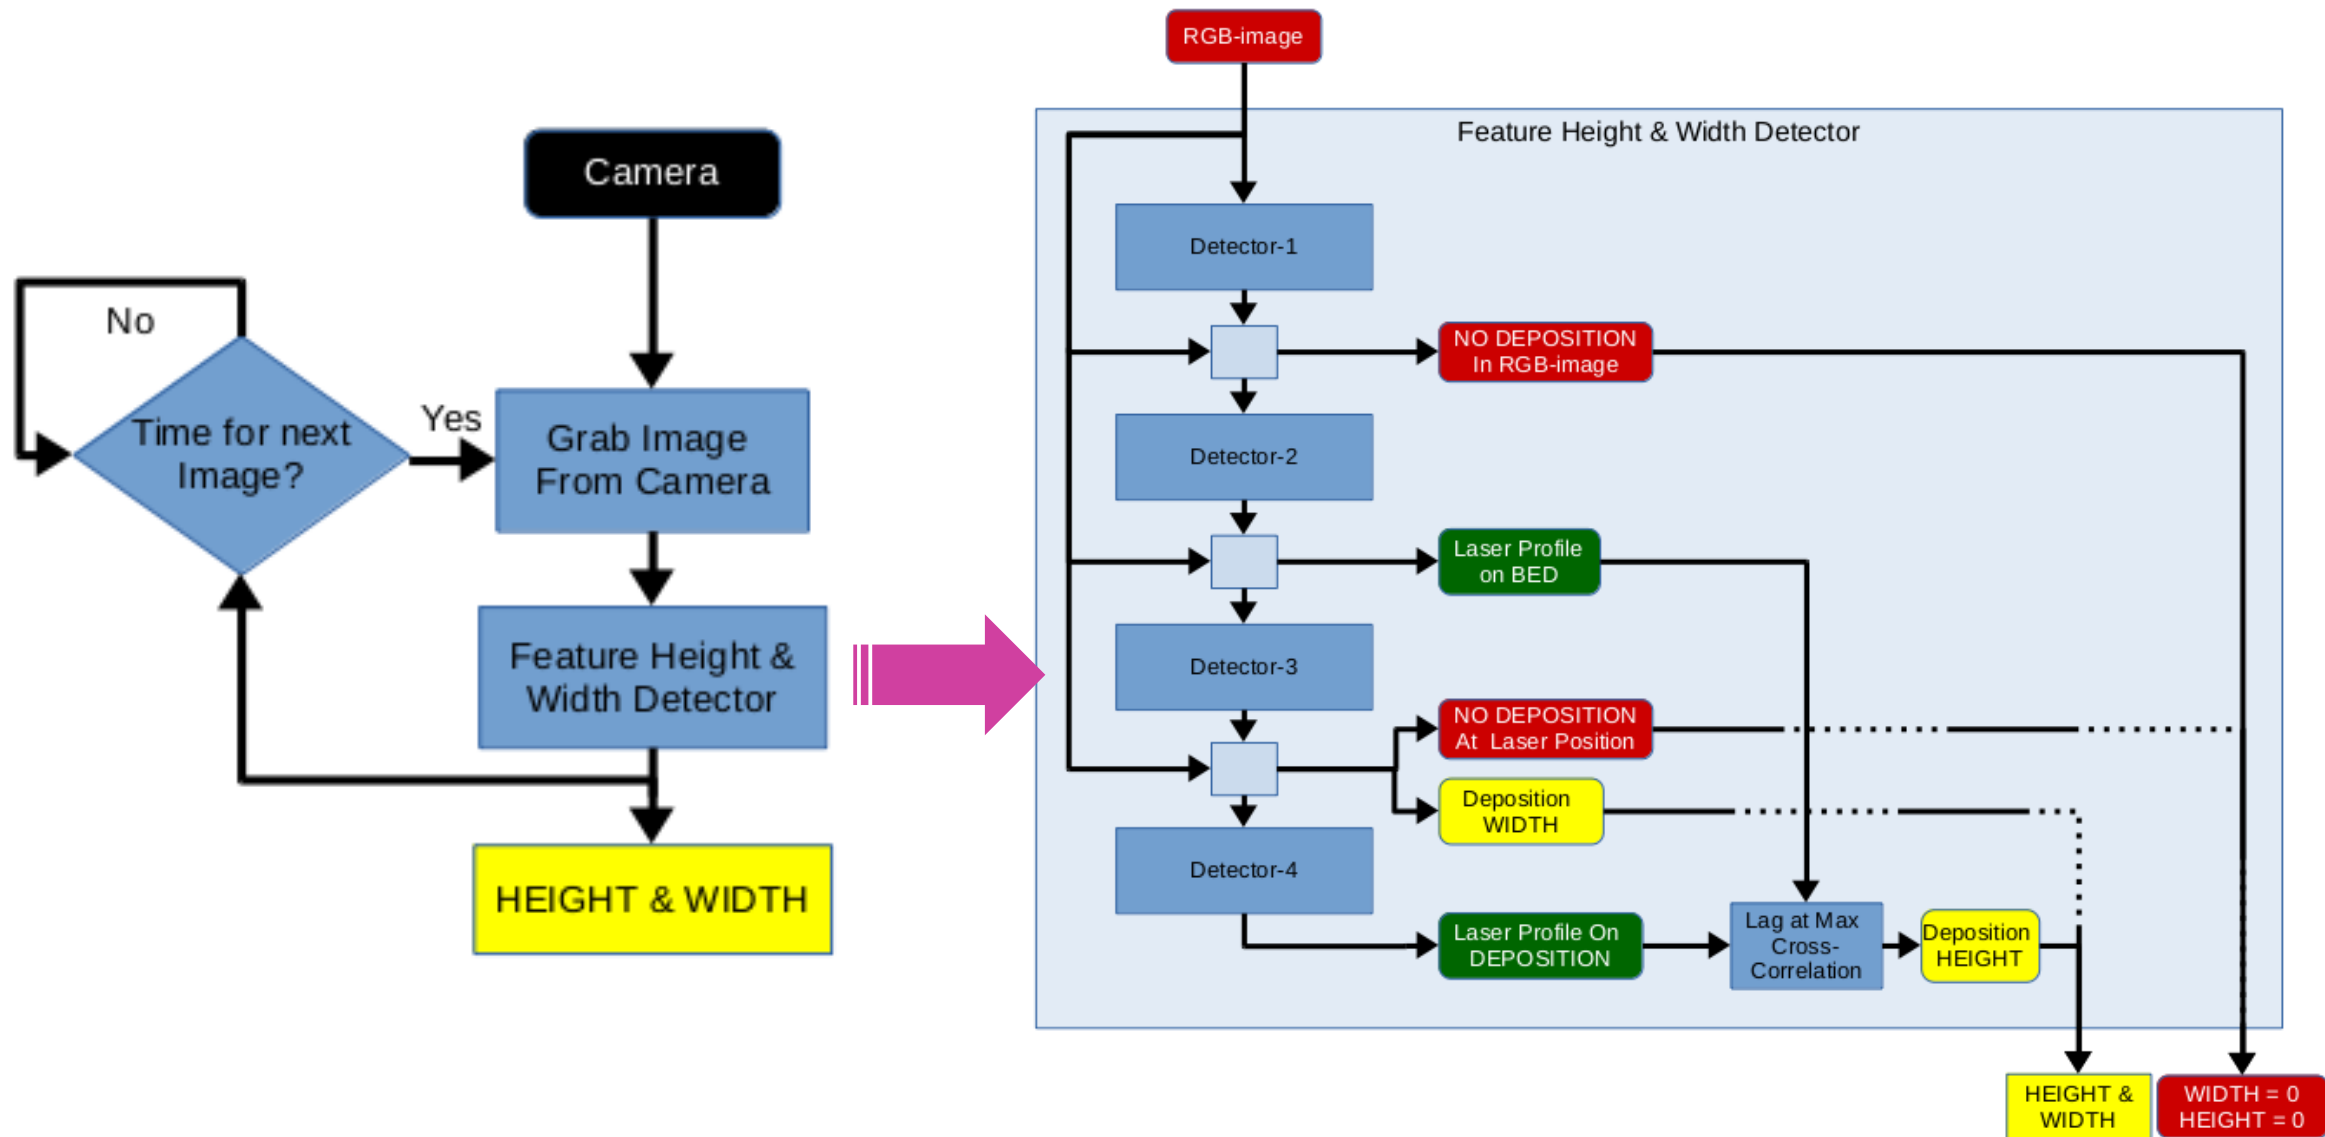

Problem Sources:	Opportunities:
<ul style="list-style-type: none">• 8-bit RGB-images (15 million integers) → Operations are costly	<ul style="list-style-type: none">• Find regions of interest → Reduce operation cost
<ul style="list-style-type: none">• Avoid common 2D computer vision operations e.g. convolution filtering, edge detection → Low Speed	<ul style="list-style-type: none">• Use fast 1D operations e.g. 1D filtering, differencing → High Speed
<ul style="list-style-type: none">• Avoid optimization algorithms → Timing consistency	<ul style="list-style-type: none">• Use consistent computational elements e.g. fixed array size → Consistency

13

Profilometry Measurement - Calibration

14

Width [um]

Width [um]

Profilometry Measurement - Validation

Steady-State Modeling - Principle

16

Inputs - Gridding:

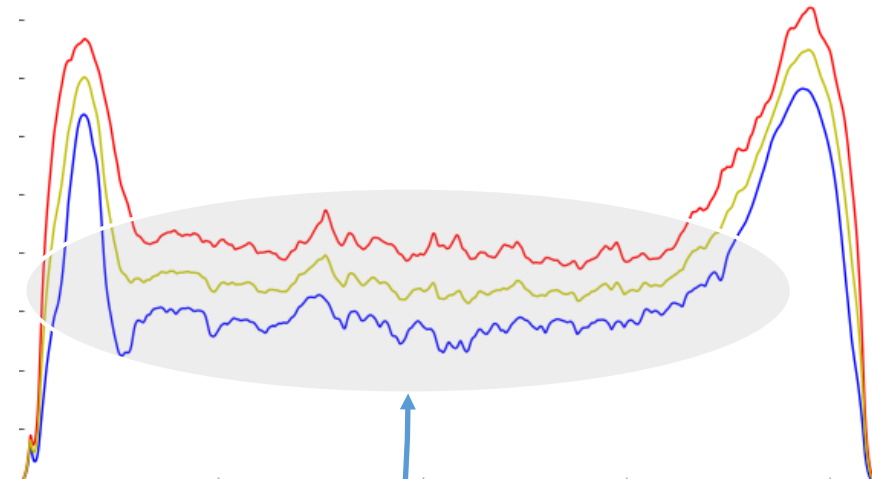

- V - Printer bed velocity
- P - Syringe pressure

Outputs:

- H - Deposition Height [μm]
- W - Deposition Width [μm]

Steady-State system identification:

- Theory: Static input \rightarrow Output @ time $\rightarrow \infty$
- Practical: Take static response part of output

Steady-State Modeling – Implementation

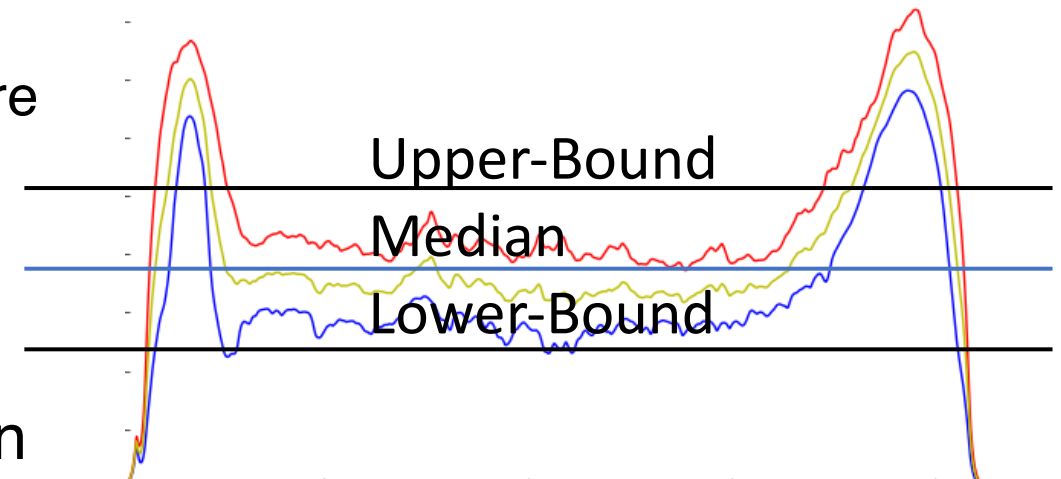

17

Input:

- Apply all static input combinations between:
 - $V \rightarrow [5, 10, 15]$ mm/s
 - $P \rightarrow [200, 250, 300, 350, 400]$ kPa
- Use multiple samples \rightarrow Account for:
 - Internal changing dynamics e.g. Temperature
 - Setup changes
 - Human error

Output:

- Median-Average-Deviation \rightarrow Detect region
- Median of region \rightarrow Sample output
- Mean of samples \rightarrow Mean output

Steady-State Modeling – Summary

Width:

- Low velocity & High pressure → Large Width
- High velocity & Low pressure → Small Width

Height:

- No clear pattern

How to use results?

- Cubic model fit → direct mapping from input to output
- Table lookup → Use interpolated grid values

Steady-State Modeling – Discussion

Paper as print foundation:

- Flexibility → foundation height changes
